

# Session 3: CSS Positioning & Layout

IML 400

"The Web is Dead"

The Internet is evolving. How?

# CSS Layout & Positioning

display

# CSS display

- block
  - `<div>`, `<p>`, `<form>`, `<header>`
  - starts on new line, stretches as far as possible
- inline
  - `<span>`, `<a>`
  - Wraps text inside a paragraph without disrupting the flow of a paragraph
- none
  - `<script>`
  - Commonly used in Javascript to hide/show elements

# CSS margin

```
#main {  
    width: 600px;  
    margin: 0 auto;  
}
```

- Setting width prevents an element from stretching
- left/right margins center
- Resize to make the browser smaller than 600px...

# CSS margin (max-width)

```
#main {  
    max-width: 600px;  
    margin: 0 auto;  
}
```

- Setting max-width improves browser's handling of small windows

# The Box Model

- Setting width can be misleading!
- Margin vs. padding
- Look up box-sizing property for another option...

CSS position

# static

```
.static {  
    position: static;  
}
```

- Default
- No special positioning

# relative

```
.relative1 {  
    position: relative;  
}
```

```
.relative2 {  
    position: relative;  
    top: -20px;  
    left: 20px;  
    background-color: red;  
    width: 500px  
}
```

# relative

- Applicable to nested elements
- Use top, right, bottom and left properties to orient

# fixed

```
.static {  
    position: fixed;  
    bottom: 0;  
    left: 0;  
    width: 300px;  
    background-color: orange;  
}
```

- Positioned relative to viewport
- Cumbersome with some browsers (i.e., IE)

# absolute

- Behaves like fixed except relative to its parent element (not the viewport)
- If no parent element, it uses the viewport
- Still moves along with scrolling (not like fixed)

# absolute

```
.relative {  
    position: relative;  
    width: 600px;  
    height: 400px;  
}
```

```
.absolute {  
    position: absolute;  
    top: 120px;  
    right: 0;  
    width: 300px;  
    height: 200px;  
}
```

CSS float

# float

- Wraps text around images

```
img {
```

```
    float: right;
```

```
    margin: 0 0 1em 1em;
```

```
}
```

# clear

- Controls the behavior of floats

```
.box {  
    float: left;  
    width: 200px;  
    height: 100px;  
    margin: 1em;  
}  
  
.after-box {  
    clear: both;  
}
```

# clear

- What happened?
  - Adding "after-box" to <section> allowed it to move below the div
  - left value cleared elements floated to the left
    - can clear "right" and "both"

CSS percentages

# percent width

- Percentage relative to the containing block
- Great for images

```
img {
```

```
    float: right;
```

```
    width: 50%;
```

```
}
```

# percent width layouts

- Precursor to responsive design
- Pros and Cons
  - More work
  - Flexibility

# media queries

- Responsive Design
- “Responds” to the browser and device
- Use @media
